

The integration dividend — three cross-sector channels with a non-zero GIM slope where sectoral models are flat

Each curve is one cross-sector channel, normalized to its own peak; the dashed red line is every sectoral model's structural zero on that axis. *Headline effects (10y): A carbon \$50/t: emissions -6.3% , tension $+6.5 \times 10^{-3}$; B severe oil shock ($\sim 15\%$ GDP): +4 importers in sovereign crisis, debt-crisis-years $\times 2.7$; C severe yield -50% : food-stress $+0.090$, protest $+0.014$. Shapes differ honestly: B threshold-stepped, C convex, A weak-but-robust.*
